Lab III: Composite Reflections

For this lab, I learned how Composite pattern can be used when objects are arranged like a tree. In the bad version, the program needs to check if the object is a Post or Thread using instanceof. If we add another type of object, we also need to change the code that display the tree.

In the fixed version, I created the ForumComponent interface. Both Post and Thread use the same interface. The Thread can also contain other components and display them by going through its children. Because of this, the client don't need to check what type of object it is using.

I also made another example using TextComponent, Chunk, Section, and Document. It works in a similar way because the document can contain sections and the sections can contain other text components. I also added Bundle as a new leaf without changing the Thread class.

According to Gamma et al. (1994), Composite lets us compose objects into tree structures and allows individual objects and groups of objects to be treated in the same way. I understand this more in the activity because both the leaf and the group can use the same interface.
